Database Definition

I created the database using SQL Server Management Studio by first creating a new database and naming it Sick. After the database was created, I added each table by right-clicking the Tables folder and selecting New Table. I then defined the columns for each table by assigning primary keys, nvarchar fields, and the appropriate data types. After, I right-clicked Database Diagrams and selected New Database Diagram. I added all of the tables to the diagram and connected them based on their relationships. For example, I linked the PatientID in the Patient table to the PatientID in the PatientAilment table to create a foreign key relationship, then I repeated this process for the other tables connecting them with their foreign keys.

Tables Diagram, and folders screen shot:

Database Population

After creating the database structure, I populated the tables with data using the provided SQL populate script from the assignment. I downloaded the script file and opened it in SQL Server Management Studio by selecting File → Open → File, then choosing the SickDBPopulate.sql file. Before running the script, I adjusted the database connections to ensure it was pointing to my Sick database. I also added the missing ProviderType insert statements so that all tables would contain data. Afterwards I executed it, which inserted records into each table. I then verified that the data appeared correctly by opening the tables and viewing the rows.
